Mitigating emissions in the transport refrigeration sector in South Africa

Introducing innovative logistics and supply structures in the South African transport refrigeration sector to mitigate emissions

The challenge

South Africa’s economy depends largely on agriculture and trade and retail – two sectors in which transport plays a vital role. The transport and distribution of refrigerated goods is an important part of the greenhouse gas emission balance of cold chains. It is estimated that under a business-as-usual scenario, emissions in the transport refrigeration sector will increase from the current two million tons of CO₂eq*, to above five million tons CO₂eq by 2020 in South Africa.

There are about 14 000 trucks and trailers in the refrigerated transport sector in South Africa. In terms of their direct greenhouse gas emissions, each truck contains refrigerants, mainly the hydrofluorocarbon blend R404a, which has a global-warming potential (GWP) of 3 922 and to a lesser extent the hydrofluorocarbon 134a (HFC-134a), which has a GWP of 1 430 times that of CO₂. Furthermore, the refrigeration unit and truck engine consume fuel and therefore create indirect emissions in the form of CO₂. These indirect emissions contribute less than 50% in smaller trucks, but up to 75% in trailers.

In 1987, 197 countries, including South Africa, ratified the Montreal Protocol on Substances that Deplete the Ozone Layer. By doing so, they committed to phase out the use of chlorofluorocarbons (CFCs) and hydrochlorofluorocarbons (HCFCs) – two substances with high ozone-depleting potential which, in the past, were commonly used in the refrigeration industry. Nowadays, HFCs are the most commonly used refrigerants in cooled transport processes in South Africa. Although these gases have no ozone-depleting potential, they can still be damaging to the environment because of their predominantly high GWP.

In order to mitigate the high level of emissions from refrigerated trucks and trailers, the type of refrigerant used needs to be reconsidered and energy-efficiency improvements have to be made. However, this poses some challenges: the refrigerated transport sector lacks the technical information and know-how to make these changes. Solutions to these challenges are not readily available and there are only a couple of transport refrigeration units in the world that are currently running on alternative natural refrigerants.

In terms of energy-efficiency improvements, the insulation of the bodies is the most important starting point. However, South Africa does not have a testing facility to measure thermal efficiency, which makes it impossible to assess the actual performance of trucks and trailers.

Our approach

With South Africa’s obligation to phase out the use of HCFCs in the foam industry and its commitment to reduce greenhouse gas emissions as expressed in the National Climate Change Response Policy White Paper of 2011, there is an opportunity to reorganise the old supply infrastructure. The project aims to contribute to the climate-friendly development of the transport refrigeration sector in South Africa through two main interventions: changing to natural refrigerants, such as hydrocarbons or carbon dioxide, with less global-warming potential, and reducing the energy consumption of the cooling and transportation process. The latter can be accomplished by:

- increasing the energy efficiency of the refrigeration system (using less energy to provide the same amount of cooling);
- increasing the insulation capacity of the vehicle bodies to reduce the cooling capacity required to reach and maintain specific temperatures; and
- optimising operational procedures such as loading practices.

The project further supports the South African government to integrate the transport refrigeration sector into their national mitigation strategy. The project will be implemented in two phases:

- In phase one, the sector has been analysed in close cooperation with relevant stakeholders in the refrigeration industry. The most promising measures and interventions to reduce greenhouse gas emissions have been formulated, assessed and discussed with the partners.
- During phase two, pilot measures are now being implemented.

Results achieved so far

After engaging with relevant stakeholders in the refrigeration industry, the sector analysis was completed and pilot measures were recommended. Two workshops were held in November 2013 and March 2014. Thereafter a steering committee was established in April 2014 to take the lead on the project. This committee comprises officials from South African Government departments, associations as well as industry representatives.

The project’s main activities are:

1. Establishing a test chamber in South Africa
   A first test facility will be installed and operated by end 2016 in order to measure the insulation capacity of refrigerated vehicle bodies. In line with this a standardization process on insulation requirements and testing procedures has been initiated at South African Bureau of Standards.

2. Improving the insulation of trucks and trailers
   Domestic manufacturers are being supported in improving the design and manufacturing processes so their products can eventually meet the requirements of the future national standard.

3. Developing a truck refrigeration unit with natural refrigerants
   A prototype working with a hydrocarbon refrigerant has been developed in cooperation with the South African transport refrigeration industry and research institutes and will be field tested in 2016.

4. Developing training courses
   Training courses on transport refrigeration technology as well as on cold chain logistics are being developed and conducted together with South African stakeholders.
