What is Climate Smart **Agriculture?**

"Agriculture that sustainably increases productivity, resilience (to climate change), reduces/removes greenhouse gases (mitigation), and enhances achievement of national food security and development goals"

Source: FAO, 2010

Climate change causes some serious challenges to the agricultural sector and therefore to the national food security and

Yields enhanced with compost and encased beds

development goals for Grenada. The table below outlines these challenges and appropriate climate smart agricultural (CSA) practices to counter them:

For Crops:

Climate change signal	Appropriate CSA practice		
Temperature Increase: heat stress or increased disease	Heat tolerant varieties, mulching,		
could reduce yields, leading to increased production costs.	water management, shade house,		
	boundary trees		
Extreme weather events: more frequent heat waves, strong	Flood tolerant plant varieties,		
winds, and storms lead to top-soil erosion, reduced yields,	rainwater harvesting, irrigation,		
and damages to trees, infrastructures and equipment (eg.	mulching, composting, contour		
hurricane).	planting, check dams, terraces to		
	plant on slopes, etc.		
Rising sea level: 3% of agricultural land could be lost due to	Saline water tolerant plant variety		
1 m, including widespread loss of agricultural land from	in coastal areas		
saline intrusion into coastal aquifers.			
Weeds, Pests and Disease: It is also possible that increases	Intercropping, crop diversity,		
in temperature, moisture and carbon dioxide could result in	mulching, container gardening and		
higher populations of destructive pests.	encased beds		
Irrigation and Rainfall: Changes in climate may also impact	Rainwater harvesting, efficient		
the water availability and water needs for agriculture. Rain	irrigation, mulching, composting,		
shortage leads to extended dry spells, and excessive rains	treated manure and nitrogen		
leads to erosion and loss of soil fertility.	fixing trees		

For Livestock:

Climate change signal	Appropriate CSA practice
Temperature: Increased air temperatures can lead to	Appropriate housing & spacing
more stress on livestock – lower reproduction &	
growth rate, increased disease & mortality rates.	
Feed Quality: Availability of forage could also decrease	Crop management practices, improved
if there is not enough water and nutrients in stressed	feeding strategies, rotational grazing
soils to keep up with plant growth.	
Diseases: Insect parasites and diseases could also	Improved livestock health
become more prolific and new diseases may also	
emerge as global warming progresses.	

Climate-smart	agricultural	practices
----------------------	--------------	-----------

Crop management	Livestock Management	Soil and water management	Agroforestry	Integrated food energy system
 Intercropping to maximise space, pest control & cash crop Crop rotations should include legumes New crop varieties (e.g. drought, wind & flood tolerant) Improved storage and processing techniques Greater crop diversity Underground crops (e.g. yams, dasheen) Stake plants to reduce wind damage Composting and organic fertilizer Mulching crops Shade house 	 Improve feeding strategies (e.g. cut 'n carry) Rotational grazing Grow suitable crops (with proper management) to feed animals eg. Leucaena & gliricidia Manure treatment (well-rotted/ decomposed) Improved livestock health Animal husbandry improvements 	 Conservation agriculture (e.g. minimum tillage) Contour planting Use mounds to plant on slopes Grass barriers (e.g. kush grass) Stone barriers Check dams Use bench/eyebrow terraces to plant on slopes Encase beds (pallets, bamboo) Water storage (e.g. rainwater harvesting) Improved irrigation (e.g. drips) 	 Boundary trees, & wind breaks Nitrogen-fixing trees on farms (e.g. legumes) Multipurpose trees (e.g. fruit trees used as windbreaker) Fruit orchards 	 Biogas Improved stoves Solar power Ram pumps for irrigation Gravity-fed irrigation system
